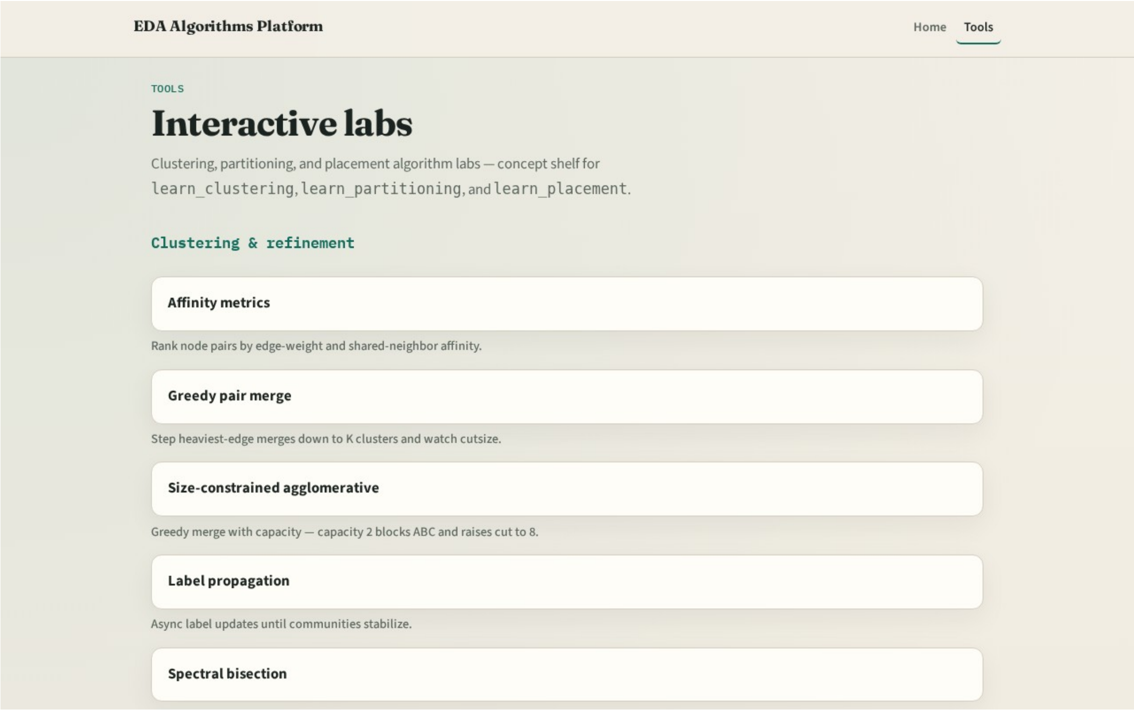
Congestion in the stack

You placed and legalized cells

Two tracks

- Track B is the browser lab: drag cells, watch heat maps, clear challenges
- Track A is implement: Python solvers on a tiny JSON instance
- Use either or both
- Browser first for intuition is fine



Course map

- Foundations cover GCells and capacity
- Estimation covers RUDY, probabilistic demand, heat maps, and overflow metrics
- Feedback covers inflators, net weights, and one placement loop
- Offline compare and wrap close the path

Prerequisites

- Finish learn_placement or learn_legalization first so float versus legal coordinates
- Density bins from placement are cousins, not the same as routing GCells

How to move

- Read each module README
- Odd module slots leave room to insert algorithms later without renumbering

Next

- Complete the quiz for this part
- Open the GCell grid model and learn the four-by-two tiling by heart
