

Why compare

Toy global routers need a harness: same JSON in, edge overflow and runtime out

The idea

- Fix tiny_gr
- Run sequential L-HV, maze mode, and one rip-up pass
- Record total overflow, max overflow, wall time
- Optionally compare to a reference router
- Write one discrepancy hypothesis

Harness shape

- A small Python driver loading `tiny_gr.json` is enough
- Print a markdown table
- Missing external tools are OK, document blockers and still validate I/O

Pitfalls

- Changing edge_capacity between rows
- Comparing incompatible route modes without labeling
- Optimizing runtime before correctness

Your turn

- Fill one comparison table for L versus maze versus rip-up
- Then open the wrap
