

Welcome to legalization

Global placement spreads cells for wirelength and density, but coordinates float freely

What you'll build

- You'll model sites and rows, check legality, greedy-snap floats, remove overlaps
- Then legalize around fixed macros, measure displacement versus HPWL
- Nine browser labs have step-by-step algorithm walkthroughs with verified goldens

Prerequisite path

- Finish **learn_placement** first: you need global-place floats and HPWL intuition
- Floorplanning and clustering further upstream set the outline

Two tracks

- Every lab offers Track A, implement on ``tiny_legal.json``
- Good rhythm: browser for row/site intuition, implement to harden checkers and packers

How to move

- Read each README, pick a track, work the checklist
- Keep legality, displacement, and HPWL as habits
- When intro checklist is done
